

# Neural networks with backprop library

Justin Le

The *backprop* library performs backpropagation over a *heterogeneous* system of relationships. It does so by letting you build an explicit graph and keeps track of what nodes depend on what. Let's use it to build neural networks!

Repository source is on [github](https://github.com/mstksg/backprop)<sup>1</sup>, and so are the rendered unstable docs<sup>2</sup>.

```

## Ops

First, we define values of `Op` for the operations we want to do. `Ops` are bundles of functions packaged with their heterogeneous gradients. For simple numeric functions, *backprop* can derive `Ops` automatically. But for matrix operations, we have to derive them ourselves.

---

<sup>1</sup><https://github.com/mstksg/backprop>

<sup>2</sup><https://mstksg.github.io/backprop>

The types help us with matching up the dimensions, but we still need to be careful that our gradients are calculated correctly.

`L` and `R` are matrix and vector types from the great *hmatrix* library.

First, matrix-vector multiplication:

```
matVec
  :: (KnownNat m, KnownNat n)
  => Op '[ L m n, R n ] (R m)
matVec = op2' $ \m v -> ( m #> v
                        , \ (fromMaybe 1 -> g) ->
                          (g `outer` v, tr m #> g)
                        )
```

Now, dot products:

```
dot :: KnownNat n
    => Op '[ R n, R n ] Double
dot = op2' $ \x y -> ( x <.> y
                    , \case Nothing -> (y, x)
                      Just g -> (konst g * y, x * konst g)
                    )
```

And for kicks, we can show an auto-derived logistic function op:

```
logistic :: Floating a => Op '[a] a
logistic = op1 $ \x -> 1 / (1 + exp (-x))
```

That's really it!

## A Simple Complete Example

At this point, we already have enough to train a simple single-hidden-layer neural network:

```
simpleOp
  :: (KnownNat m, KnownNat n, KnownNat o)
  => R m
  -> BPOp s '[ L n m, R n, L o n, R o ] (R o)
simpleOp inp = withInps $ \(w1 :< b1 :< w2 :< b2 :< Ø) -> do
  -- First layer
  y1 <- matVec -$ (w1 :< x1 :< Ø)
  z1 <- op2 (+) -$ (y1 :< b1 :< Ø)
  x2 <- logistic -$ only z1
  -- Second layer
  y2 <- matVec -$ (w2 :< x2 :< Ø)
  z2 <- op2 (+) -$ (y2 :< b2 :< Ø)
  logistic -$ only z2
  where
    x1 = constRef inp
```

Now `simpleOp` can be “run” with the input vectors and parameters (`a L n m, R n, L o n, R o`, etc.) and calculate the output of the neural net.

```
runSimple
  :: (KnownNat m, KnownNat n, KnownNat o)
  => R m
```

```

-> Tuple '[ L n m, R n, L o n, R o ]
-> R o
runSimple inp = runBPOp (simpleOp inp)

```

But, in defining `simpleOp`, we also generated a graph that *backprop* can use to do backpropagation, too!

```

simpleGrad
  :: forall m n o. (KnownNat m, KnownNat n, KnownNat o)
  => R m
  -> R o
  -> Tuple '[ L n m, R n, L o n, R o ]
  -> Tuple '[ L n m, R n, L o n, R o ]
simpleGrad inp targ params = gradBPOp opError params
  where
    opError :: BPOp s '[ L n m, R n, L o n, R o ] Double
    opError = do
      res <- simpleOp inp
      err <- op2 (-) -$ (res :< t      :< ∅)
      dot          -$ (err :< err :< ∅)
    where
      t = constRef targ

```

The result is the gradient of the input tuple’s components, with respect to the `Double` result of `opError` (the squared error). We can then use this gradient to do gradient descent.

## With Parameter Containers

This method doesn’t quite scale, because we might want to make networks with multiple layers and parameterize networks by layers. Let’s make some basic container data types to help us organize our types, including a recursive `Network` type that lets us chain multiple layers.

```

data Layer :: Nat -> Nat -> Type where
  Layer :: { _lWeights :: L m n
            , _lBiases  :: R m
            }
            -> Layer n m
  deriving (Show, Generic)

data Network :: Nat -> [Nat] -> Nat -> Type where
  N∅    :: !(Layer a b) -> Network a '[ ] b
  (:&)  :: !(Layer a b) -> Network b bs c -> Network a (b ': bs) c

```

A `Layer n m` is a layer taking an `n`-vector and returning an `m`-vector. A `Network a '[b, c, d] e` would be a `Network` that takes in an `a`-vector and outputs an `e`-vector, with hidden layers of sizes `b`, `c`, and `d`.

## Isomorphisms

The *backprop* library lets you apply operations on “parts” of data types (like on the weights and biases of a `Layer`) by using `Iso`’s (isomorphisms), like the ones from the *lens* library. The library doesn’t depend on *lens*, but it can use the `Isos` from the library and also custom-defined ones.

First, we can auto-generate isomorphisms using the *generics-sop* library:

```
instance SOP.Generic (Layer n m)
```

And then can create isomorphisms by hand for the two Network constructors:

```
netExternal :: Iso' (Network a '[] b) (Tuple '[Layer a b])
netExternal = iso (\case NØ x      -> x ::< Ø)
                  (\case I x :< Ø -> NØ x      )

netInternal :: Iso' (Network a (b '[: bs] c) (Tuple '[Layer a b, Network b bs c])
netInternal = iso (\case x :& xs      -> x ::< xs ::< Ø)
                  (\case I x :< I xs :< Ø -> x :& xs      )
```

An `Iso' a (Tuple as)` means that an `a` can really just be seen as a tuple of `as`.

## Running a network

Now, we can write the `BPOp` that represents running the network and getting a result. We pass in a `Sing bs` (a singleton list of the hidden layer sizes) so that we can “pattern match” on the list and handle the different network constructors differently.

```
netOp
  :: forall s a bs c. (KnownNat a, KnownNat c)
  => Sing bs
  -> BPOp s '[ R a, Network a bs c ] (R c)
netOp sbs = go sbs
where
  go :: forall d es. KnownNat d
    => Sing es
    -> BPOp s '[ R d, Network d es c ] (R c)
go = \case
  SNil -> withInps $ \(x :< n :< Ø) -> do
    -- peek into the NØ using netExternal iso
    l :< Ø <- netExternal #<~ n
    -- run the 'layerOp' op, with x and l as inputs
    layerOp ~$ (x :< l :< Ø)
  SNat `SCons` ses -> withInps $ \(x :< n :< Ø) -> withSingI ses $ do
    -- peek into the (:&) using the netInternal iso
    l :< n' :< Ø <- netInternal #<~ n
    -- run the 'layerOp' BP, with x and l as inputs
    z <- layerOp ~$ (x :< l :< Ø)
    -- run the 'go ses' BP, with z and n as inputs
    go ses ~$ (z :< n' :< Ø)
  layerOp
    :: forall d e. (KnownNat d, KnownNat e)
    => BPOp s '[ R d, Layer d e ] (R e)
  layerOp = withInps $ \(x :< l :< Ø) -> do
    -- peek into the layer using the gTuple iso, auto-generated with SOP.Generic
    w :< b :< Ø <- gTuple #<~ l
    y <- matVec -$ (w :< x :< Ø)
    z <- op2 (+) -$ (y :< b :< Ø)
    logistic -$ only z
```

There’s some singletons work going on here, but it’s fairly standard singletons stuff. From *backprop* specifically, `(#<~)` lets you “split” an input ref with the given iso, and `(~$)` lets you “run” an BP within an BP, by

plugging in its inputs.

## Gradient Descent

Now we can do simple gradient descent. Defining an error function:

```
err
  :: KnownNat m
  => R m
  -> BPrep s rs (R m)
  -> BPOp s rs Double
err targ r = do
  d <- opRef2 r t $ op2 (-)
  opRef2 d d      $ dot
  where
    t = constRef targ
```

And now, we can use `backprop` to generate the gradient, and shift the `Network`! Things are made a bit cleaner from the fact that `Network a bs c` has a `Num` instance, so we can use `(-)` and `(*)` etc.

```
train
  :: (KnownNat a, SingI bs, KnownNat c)
  => Double
  -> R a
  -> R c
  -> Network a bs c
  -> Network a bs c
train r x t n = case backprop (err t =<< netOp sing) (x ::< n ::< ∅) of
  (_, _ :< I g :< ∅) -> n - (realToFrac r * g)
```

((::<) is cons and ∅ is nil for tuples.)

## Main

`main`, which will train on sample data sets, is still in progress! Right now it just generates a random network using the *mwc-random* library and prints each internal layer.

```
main :: IO ()
main = withSystemRandom $ \g -> do
  n <- uniform @ (Network 4 '[3,2] 1) g
  void $ traverseNetwork sing (\l -> l <$ print l) n
```

## Appendix: Boilerplate

And now for some typeclass instances and boilerplates unrelated to the *backprop* library that makes our custom types easier to use.

```
instance KnownNat n => Variate (R n) where
  uniform g = randomVector <$> uniform g <*> pure Uniform
  uniformR (l, h) g = (\x -> x * (h - l) + l) <$> uniform g

instance (KnownNat m, KnownNat n) => Variate (L m n) where
```

```

uniform g = uniformSample <$> uniform g <*> pure 0 <*> pure 1
uniformR (l, h) g = (\x -> x * (h - l) + l) <$> uniform g

instance (KnownNat n, KnownNat m) => Variate (Layer n m) where
uniform g = subtract 1 . (* 2) <$> (Layer <$> uniform g <*> uniform g)
uniformR (l, h) g = (\x -> x * (h - l) + l) <$> uniform g

instance (KnownNat m, KnownNat n) => Num (Layer n m) where
Layer w1 b1 + Layer w2 b2 = Layer (w1 + w2) (b1 + b2)
Layer w1 b1 - Layer w2 b2 = Layer (w1 - w2) (b1 - b2)
Layer w1 b1 * Layer w2 b2 = Layer (w1 * w2) (b1 * b2)
abs (Layer w b) = Layer (abs w) (abs b)
signum (Layer w b) = Layer (signum w) (signum b)
negate (Layer w b) = Layer (negate w) (negate b)
fromInteger x = Layer (fromInteger x) (fromInteger x)

instance (KnownNat m, KnownNat n) => Fractional (Layer n m) where
Layer w1 b1 / Layer w2 b2 = Layer (w1 / w2) (b1 / b2)
recip (Layer w b) = Layer (recip w) (recip b)
fromRational x = Layer (fromRational x) (fromRational x)

instance (KnownNat a, SingI bs, KnownNat c) => Variate (Network a bs c) where
uniform g = genNet sing (uniform g)
uniformR (l, h) g = (\x -> x * (h - l) + l) <$> uniform g
