Neural networks with backprop library

Justin Le

The backprop library performs backpropagation over a hetereogeneous system of relationships. It does so by letting you build an explicit graph and keeps track of what nodes depend on what. Let's use it to build neural networks!

Repository source is on github, and so are the rendered unstable docs.

```

Ops

First, we define values of Op for the operations we want to do. Ops are bundles of functions packaged with their hetereogeneous gradients. For simple numeric functions, *backprop* can derive Ops automatically. But for matrix operations, we have to derive them ourselves.

The types help us with matching up the dimensions, but we still need to be careful that our gradients are calculated correctly.

L and R are matrix and vector types from the great hmatrix library.

First, matrix-vector multiplication:

```
matVec
    :: (KnownNat m, KnownNat n)
    => Op '[ L m n, R n ] (R m)
matVec = op2' $ \m v \rightarrow ( m #> v
                           , \backslash (fromMaybe 1 \rightarrow g) \rightarrow
                                 (g `outer` v, tr m #> g)
Now, dot products:
dot :: KnownNat n
    => Op '[ R n, R n ] Double
dot = op2' \$ \x y -> (x <.> y
                       , \case Nothing -> (y, x)
                                Just g -> (konst g * y, x * konst g)
And for kicks, we can show an auto-derived logistic function op:
logistic :: Floating a => Op '[a] a
logistic = op1 x \sim 1 / (1 + exp (-x))
That's really it!
```

A Simple Complete Example

At this point, we already have enough to train a simple single-hidden-layer neural network:

```
simpleOp
```

```
:: (KnownNat m, KnownNat n, KnownNat o)
      => R m
      -> R o
     -> BPOp s '[ L n m, R n, L o n, R o ] Double
simpleOp inp targ = withInps \ \(w1 :< b1 :< w2 :< b2 :< \(\emline{Q}\)) -> do
    -- First layer
    y1 <- opRef2 w1 x1 $ matVec
    z1 <- opRef2 y1 b1 $ op2 (+)
    x2 <- opRef1 z1
                        $ logistic
    -- Second layer
    y2 <- opRef2 w2 x2 $ matVec
    z2 <- opRef2 y2 b2 $ op2 (+)
    out <- opRef1 z2
                        $ logistic
    -- Return error squared
    err <- opRef2 out t $ op2 (-)
    opRef2 err err
                        $ dot
  where
    x1 = constRef inp
    t = constRef targ
```

Now simpleOp can be "run" with the input vectors and parameters (a L n m, R n, L o n, R o, etc.) and calculate their gradients on the final Double result (the squared error).

```
simpleGrad
```

```
:: (KnownNat m, KnownNat n, KnownNat o)
```

```
=> R m
-> R o
-> Tuple '[ L n m, R n, L o n, R o ]
-> (Double, Tuple '[L n m, R n, L o n, R o])
simpleGrad inp targ params = backprop (simpleOp inp targ) params
```

The resulting tuple gives the network's squared error along with the gradient along all of the input tuple.

With Parameter Containers

This method doesn't quite scale, because we might want to make networks with multiple layers and parameterize networks by layers. Let's make some basic container data types to help us organize our types, including a recursive Network type that lets us chain multiple layers.

A Layer n m is a layer taking an n-vector and returning an m-vector. A Network a '[b, c, d] e would be a Network that takes in an a-vector and outputs an e-vector, with hidden layers of sizes b, c, and d.

Isomorphisms

The backprop library lets you apply operations on "parts" of data types (like on the weights and biases of a Layer) by using Iso's (isomorphisms), like the ones from the lens library. The library doesn't depend on lens, but it can use the Isos from the library and also custom-defined ones.

First, we can auto-generate isomorphisms using the *generics-sop* library:

```
instance SOP.Generic (Layer n m)
```

And then can create isomorphisms by hand for the two Network constructors:

An Iso' a (Tuple as) means that an a can really just be seen as a tuple of as.

Running a network

Now, we can write the BPOp that reprenents running the network and getting a result. We pass in a Sing bs (a singleton list of the hidden layer sizes) so that we can "pattern match" on the list and handle the different network constructors differently.

```
net0p
    :: forall s a bs c. (KnownNat a, KnownNat c)
    => Sing bs
    -> BPOp s '[ R a, Network a bs c ] (R c)
netOp sbs = go sbs
  where
    go :: forall d es. KnownNat d
        => Sing es
        -> BPOp s '[ R d, Network d es c ] (R c)
    go = \case
      SNil -> withInps \ \ (x :< n :< \emptyset) -> do
        -- peek into the NØ using netExternal iso
        1 :< Ø
                     <- netExternal #<~ n
        -- run the 'layerOp' op, with x and l as inputs
        layerOp ~$ x :< 1 :< ∅
      SNat `SCons` ses -> withInps \ (x :< n :< \emptyset) -> withSingI ses \ do
        -- peek into the (:8) using the netInternal iso
        l :< n' :< ∅ <- netInternal #<~ n
        -- run the 'layerOp' BP, with x and l as inputs
        z <- layerOp ~$ x :< l :< Ø
        -- run the 'go ses' BP, with z and n as inputs
                     ~$ z :< n' :< Ø
        go ses
    layer0p
        :: forall d e. (KnownNat d, KnownNat e)
        => BPOp s '[ R d, Layer d e ] (R e)
    layerOp = withInps (x : < 1 : < \emptyset) -> do
        -- peek into the layer using the qTuple iso, auto-generated with SOP. Generic
        w :< b :< ∅ <- gTuple #<~ l
                    <- opRef2 w x matVec</pre>
        у
                    <- opRef2 y b (op2 (+))
        opRef1 y' logistic
```

There's some singletons work going on here, but it's fairly standard singletons stuff. From *backprop* specifically, (#<~) lets you "split" an input ref with the given iso, and (~\$) lets you "run" an BP within an BP, by plugging in its inputs.

Gradient Descent

Now we can do simple gradient descent. Defining an error function:

```
:: KnownNat m
=> R m
-> BPRef s rs (R m)
-> BPOp s rs Double
err targ r = do
   d <- opRef2 r t $ op2 (-)
   opRef2 d d $ dot</pre>
```

```
where
   t = constRef targ
```

And now, we can use backprop to generate the gradient, and shift the Network! Things are made a bit cleaner from the fact that Network a bs c has a Num instance, so we can use (-) and (*) etc.

train
 :: (KnownNat a, SingI bs, KnownNat c)
 => Double
 -> R a
 -> R c
 -> Network a bs c
 -> Network a bs c
train r x t n = case backprop (err t =<< netOp sing) (x ::< n ::< 0) of
 (_, _ :< I g :< 0) -> n - (realToFrac r * g)
((::<) is cons and 0 is nil for tuples.)</pre>

Main

main, which will train on sample data sets, is still in progress! Right now it just generates a random network using the *mwc-random* library and prints each internal layer.

```
main :: IO ()
main = withSystemRandom $ \g -> do
    n <- uniform @(Network 4 '[3,2] 1) g
    void $ traverseNetwork sing (\l -> 1 <$ print 1) n</pre>
```

Appendix: Boilerplate

And now for some typeclass instances and boilerplates unrelated to the *backprop* library that makes our custom types easier to use.

```
instance KnownNat n => Variate (R n) where
    uniform g = randomVector <$> uniform g <*> pure Uniform
    uniformR (1, h) g = (\x -> x * (h - 1) + 1) < $ uniform g
instance (KnownNat m, KnownNat n) => Variate (L m n) where
    uniform g = uniformSample <$> uniform g <*> pure 0 <*> pure 1
    uniformR (1, h) g = (\x -> x * (h - 1) + 1) < \ uniform g
instance (KnownNat n, KnownNat m) => Variate (Layer n m) where
    uniform g = subtract 1 . (* 2) <$> (Layer <$> uniform g <*> uniform g)
   uniformR (1, h) g = (\x -> x * (h - 1) + 1) < \ uniform g
instance (KnownNat m, KnownNat n) => Num (Layer n m) where
   Layer w1 b1 + Layer w2 b2 = Layer (w1 + w2) (b1 + b2)
   Layer w1 b1 - Layer w2 b2 = Layer (w1 - w2) (b1 - b2)
   Layer w1 b1 * Layer w2 b2 = Layer (w1 * w2) (b1 * b2)
           (Layer w b) = Layer (abs w) (abs b)
    signum (Layer w b) = Layer (signum w) (signum b)
   negate (Layer w b) = Layer (negate w) (negate b)
   fromInteger x = Layer (fromInteger x) (fromInteger x)
```

```
instance (KnownNat m, KnownNat n) => Fractional (Layer n m) where
    Layer w1 b1 / Layer w2 b2 = Layer (w1 / w2) (b1 / b2)
